Last time: Problems at small  $h$ , nasty likelihood curves

All likelihood curves for  $\bar{\theta}_{\text{GW}}$ :

Likelihood curves

## Drop PSR terms from model?

$$f_{\text{measured}} = f_{\text{emitted}} g(\tau; \bar{\theta}) \quad (1)$$

with

$$g(\tau; \bar{\theta}) = 1 - \frac{1}{2} \frac{H_{ij} q^i q^j}{(1 + \bar{n} \cdot \bar{q})} [\cos(-\Omega\tau + \Phi_0) - \cos(-\Omega\tau + \Phi_0 + \Omega(1 + \bar{n} \cdot \bar{q})d)] \quad (2)$$

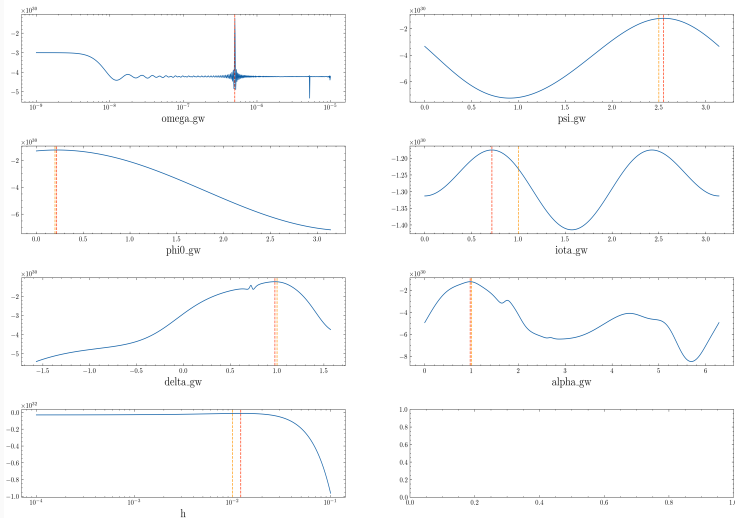

Generate the fake data using the full expression for  $g(\tau; \bar{\theta})$ , but use  $g'(\tau; \bar{\theta})$  in the Kalman measurement model

$$g'(\tau; \bar{\theta}) = 1 - \frac{1}{2} \frac{H_{ij} q^i q^j}{(1 + \bar{n} \cdot \bar{q})} [\cos(-\Omega\tau + \Phi_0)] \quad (3)$$

# Drop PSR terms from model?

All likelihood curves for  $\bar{\theta}_{\text{GW}}$ :

Likelihood curves, excluding PSR terms from model

Full NS search for **all parameters**

$$\bar{\theta} = [\bar{\theta}_{\text{GW}}, f, (t=0) \dot{f}(t=0)]$$

with  $h = 10^{-10}$ ,  $\sigma_m = 10^{-11}$

Note: pulsar distance is no longer part of model.  $\gamma$  doesn't matter

Next steps:

- Bayes factors vs. strain (currently running)
- Process noise  $\sigma_p$
- Looser priors on  $f, \dot{f}$ ? Do we need to?
- Can we add PSR terms back in? Do we need to?

**Fin.**

# Backup slides

Sometimes, it is useful to add slides at the end of your presentation to refer to during audience questions.

The best way to do this is to include the `appendixnumberbeamer` package in your preamble and call `\appendix` before your backup slides.

**metropolis** will automatically turn off slide numbering and progress bars for slides in the appendix.

## Where did $\sigma_m$ value come from?

The measurement noise is

$$\sigma_m = f \frac{\sigma_{\text{TOA}}}{\text{cadence}}$$

So for a MSP (  $f \sim 100\text{Hz}$ ) observed with a weekly cadence and  $\sigma_{\text{TOA}} \sim 1\mu\text{s}$ :

$$\sigma_m \sim 1.6 \times 10^{-10}$$

The very best pulsars might have  $\sigma_{\text{TOA}} \sim 10 \text{ ns}$ :

$$\sigma_m \sim 1.6 \times 10^{-12}$$

# $\gamma$ likelihood

# What changed?

AM: What changed such that now everything works?

- Dropping PSR terms to smooth likelihoods
- *Increasing* measurement noise
- Don't need too many live points
- Non-default Bilby sampler settings
  - e.g. docs recommend 'sample=act-walk' or 'sample=acceptance-walk'
  - More success with 'sample=rwalk-dynesty' (not 'sample=rwalk' which is the Bilby implementation)
- Be mindful of float errors - Python/Numpy/Bilby Nans get propagated, rather than error e.g. Fortran.

Example:  $\mathcal{L}(\delta)$

Example:  $\mathcal{L}(\delta)$ , zoomed 1

Example:  $\mathcal{L}(\delta)$ , zoomed 2

Example:  $\mathcal{L}(\omega)$

Example:  $\mathcal{L}(\omega)$ , zoomed 1

Example:  $\mathcal{L}(\omega)$ , zoomed 2

- Problem = overly narrow, biased posteriors
- Cause: noisy, likelihoods which are "locally Gaussian". Sampling gets stuck in a local optima and infers posteriors widths based on that optima.

Potential solutions:

1. Better settings for sampler? E.g. more live points (how many?), massively parallel, optimized likelihood evaluations,...
2. Maximum likelihood / loss optimisation?
3. Drop PSR terms from model?
4. MCMC at higher temperatures (trades off evidence..., less efficient )
5. other...?

## Option 2: Drop PSR terms from model?

OK, but some biases. c.f. location of the maxima on the previous slide

Lets proceed using this 'Earth terms' model for now.

So far we have been considering inference of only the GW terms  $\bar{\theta}_{\text{GW}}$ . It is important to be able to infer the pulsar terms  $\bar{\theta}_{\text{PSR}}$ .

Lets try and include  $f(t=0)$  and  $\dot{f}(t=0)$  in our nested sampling.

We have a uniform prior of  $\pm 1\%$  about the true value for these two parameters

# Earth terms model $\bar{\theta}_{GW}$ and $f(t=0), \dot{f}(t=0)$
